

## Storage and Release of Soluble Hexavalent Chromium from Chromate Conversion Coatings Equilibrium Aspects of $\text{Cr}^{\text{VI}}$ Concentration

Lin Xia,<sup>a</sup> Ejii Akiyama,<sup>b</sup> Gerald Frankel,<sup>b</sup> and Richard McCreery<sup>a</sup>

<sup>a</sup>Department of Chemistry and <sup>b</sup>Department of Materials Science and Engineering, The Ohio State University

The release of soluble  $\text{Cr}^{\text{VI}}$  species by a chromate conversion coating (CCC) was monitored quantitatively by ultraviolet-visible spectroscopy. By careful selection of measurement wavelength (339 nm), the  $\text{Cr}^{\text{VI}}$  concentration could be determined without regard to solution pH or  $\text{Cr}^{\text{VI}}$  speciation. The  $\text{Cr}^{\text{VI}}$  concentration in solution over a CCC reached an equilibrium value that depended on pH, ionic strength, and the ratio of the CCC surface area to the solution volume ( $A/V$ ). In separate experiments, the adsorption of  $\text{Cr}^{\text{VI}}$  by synthetic  $\text{Cr}^{\text{III}}$  hydroxide to form a  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide was observed, and also led to an equilibrium concentration of  $\text{Cr}^{\text{VI}}$  in solution. The equilibrium  $\text{Cr}^{\text{VI}}$  concentration was determined for a variety of  $A/V$  values on both AA1100 and AA2024-T3 aluminum alloys. The results are inconsistent with release mechanisms based on the solubility of a  $\text{Cr}^{\text{VI}}$  salt in the solution or depletion of  $\text{Cr}^{\text{VI}}$  from the CCC. However, the observed concentrations are consistent with a mechanism similar to a Langmuirian adsorption-desorption equilibrium of  $\text{Cr}^{\text{VI}}$  on a porous, insoluble  $\text{Cr}^{\text{III}}$  hydroxide matrix. The  $\text{Cr}^{\text{III}}$  hydroxide matrix has a finite number of  $\text{Cr}^{\text{VI}}$  binding sites and exhibits a nonlinear relationship between solution and solid  $\text{Cr}^{\text{VI}}$  concentrations governed by an equation similar to a Langmuir adsorption isotherm. The proposed model incorporates reversible adsorption and de-sorption of  $\text{Cr}^{\text{VI}}$ , with adsorption favored at low pH during formation of the CCC, and desorption favored in field conditions. The model quantitatively predicts the observed concentrations after determining the binding constant from fits to the data. The model explains the capacity of a CCC to release active  $\text{Cr}^{\text{VI}}$  corrosion inhibitor and provides strong evidence that  $\text{Cr}^{\text{VI}}$  storage in a CCC involves reversible formation of a  $\text{Cr}^{\text{VI}}\text{-O-Cr}^{\text{III}}$  mixed oxide.

It is generally accepted that  $\text{Cr}^{\text{VI}}$  in chromate conversion coatings (CCCs) and in  $\text{SrCrO}_4$  containing primers<sup>c</sup> is the critical component in corrosion protective coating systems used on aluminum aircraft alloys such as AA-2024-T3. The ability of a CCC to release  $\text{Cr}^{\text{VI}}$  as soluble chromate species is likely to be important to “self-healing” exhibited by CCCs, in which  $\text{CrO}_4^{2-}$  or related species can migrate to defects or corrosion sites and inhibit further damage.<sup>1-8</sup> Several investigators have reported that CCCs contain both  $\text{Cr}^{\text{III}}$  and  $\text{Cr}^{\text{VI}}$ <sup>9-11</sup> and a  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide has been identified as a major CCC component.<sup>12</sup> Furthermore, release of  $\text{CrO}_4^{2-}$  from a CCC has been demonstrated, as has protection of an initially untreated alloy surface by dilute  $\text{CrO}_4^{2-}$  in a chloride solution.<sup>7</sup> The mechanism of corrosion protection by chromate is currently being debated, but storage and release of  $\text{Cr}^{\text{VI}}$  by a CCC appear to be essential for its long term protection property. In addition, release of chromate from sparingly soluble  $\text{SrCrO}_4$  in primers may also provide a source of dilute chromate for self-healing.

The current investigation addresses the storage and release of  $\text{Cr}^{\text{VI}}$  in more detail. The release of  $\text{Cr}^{\text{VI}}$  from a CCC and  $\text{SrCrO}_4$  into water and salt solution was monitored quantitatively with ultraviolet-visible (UV-vis) spectroscopy, in order to examine solution concentrations,

saturation (if any), release rate, and possibly storage mechanism. By considering a variety of conditions, a quantitative model for  $\text{Cr}^{\text{VI}}$  storage and release was formulated, and its implications for corrosion protection were considered. The kinetics and rate-controlling factors during release will be addressed in a separate communication.

## Experimental

All the chemicals used were analytical grade. Solutions were prepared with “deionized” water (Barnstead, Nanopure 18  $\text{M}\Omega\text{-cm}$ ). The absorbance vs. concentration behavior of chromate solutions is complicated by the equilibria between  $\text{HCrO}_4^-$ ,  $\text{CrO}_4^{2-}$ , and  $\text{Cr}_2\text{O}_7^{2-}$ , which depend on both concentration and pH.<sup>13-17</sup> The combined concentration of these species in solution is indicated herein as  $[\text{Cr}^{\text{VI}}]$ . In order to determine the relationship between UV-vis absorbance and  $[\text{Cr}^{\text{VI}}]$ , solutions of  $\text{K}_2\text{Cr}_2\text{O}_7$  were prepared at various concentrations in the range of  $1.0 \times 10^{-5}$  M to  $4 \times 10^{-4}$  M of  $\text{Cr}^{\text{VI}}$ , and adjusted to different pH values with  $\text{HClO}_4$  or  $\text{NaOH}$  and a pH meter. UV-vis absorption spectra for solutions in 1 cm quartz cuvettes were collected using either a Perkin Elmer Lambda 20 spectrometer or a custom system based on an ISA Triax monochromator. Spectra for one  $\text{Cr}^{\text{VI}}$  concentration are shown in Fig. 1 for a pH range from 2.01-9.47. Since the absorption at 339 nm ( $A_{339}$ ) was independent of pH, this wavelength was used to construct the pH-independent calibration curve shown in Fig. 2. The absorbance at 339 nm was preferable to that at 295 nm for quantitative analysis of  $[\text{Cr}^{\text{VI}}]$  due to the smaller interference from nitrate ion. Over the range of total  $[\text{Cr}^{\text{VI}}]$  from  $1 \times 10^{-5}$  to  $4 \times 10^{-4}$  M and pH range 2.0 to 9.5,  $A_{339}$  is linear with total  $[\text{Cr}^{\text{VI}}]$ . This calibration curve was used to determine  $[\text{Cr}^{\text{VI}}]$  from observed  $A_{339}$  in subsequent experiments. The molar absorptivity in terms of total  $\text{Cr}^{\text{VI}}$  concentration is  $1.48 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$  at 339 nm over the pH range 2-9.5.

Figure 1. UV-vis spectra of  $8.3 \times 10^{-5}$  M  $\text{Cr}^{\text{VI}}$  as a function of pH. Path length was 1 cm. A is the observed absorbance.

Figure 2. Calibration line of  $A_{339\text{nm}}$  vs. total  $\text{Cr}^{\text{VI}}$  concentration. The  $8.3 \times 10^{-5} \text{ M}$  point (•) is the average of 12 samples with the same  $[\text{Cr}^{\text{VI}}]$ , but pH 2.01-9.47. All other points are the average of four samples with the same  $[\text{Cr}^{\text{VI}}]$  concentration, but pH 5-6.

$\text{Cr}^{\text{VI}}$  concentrations in solution were determined spectrophotometrically as a function of time for several starting conditions, including a CCC in water or salt solution,  $\text{Cr}^{\text{III}/\text{VI}}$  mixed oxide in water, and  $\text{Cr}^{\text{III}}$  hydroxide immersed in dilute  $\text{Cr}^{\text{VI}}$  solution. CCC films were prepared by dipping polished AA2024-T3 alloy or AA1100 alloy (polished with  $\text{Al}_2\text{O}_3/\text{H}_2\text{O}$  slurries as described in Ref. 7) into freshly prepared Alodine coating solution (Alodine 1200, 7.5 g/L, pH 1.3) at room temperature for 1 min, washing with more than 100 mL flowing water, and then air drying for various periods of time (indicated below). Then the coupons were immersed in a known volume of deionized water or 0.1 M NaCl, in well-sealed glass containers.  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed-oxide was prepared as described previously.<sup>12</sup> A known weight of freshly prepared  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide was weighed and dried on a small piece of glass in air for known periods of time. The dried  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed-oxide powder samples on glass were immersed in known volumes of Nanopure water or 0.1 M NaCl solution and tightly covered. The containers were agitated occasionally over a period of several days. Aliquots (2-3 mL) of each solution were withdrawn periodically for UV-vis spectroscopy, then returned to the corresponding container.  $[\text{Cr}^{\text{VI}}]$  released from the CCC film or mixed-oxides was determined from the absorbance at 339.0 nm. The details of CCC surface/volume ratio and  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed-oxide mass/volume ratio are listed in Table I.

Saturation concentrations of  $\text{SrCrO}_4$  in deionized water or 0.1 M NaCl were obtained by adding 2 g of  $\text{SrCrO}_4$  to 100 ml Nanopure water or 0.1 M NaCl, and stirring for 6 days. After centrifugation, 1.00 mL of supernatant was diluted to 50.00 mL with 2 M NaOH, then a UV-vis spectrum was obtained. The  $\text{CrO}_4^{2-}$  concentration was determined from the molar absorptivity at 373 nm,  $4884 \text{ M}^{-1} \text{ cm}^{-1}$ . For experiments in which the sample was not reused, such as  $\text{SrCrO}_4$  saturation and the pH effects described below, it was more convenient to dilute the sample with NaOH and determine the absorbance at 373 rather than 339 nm. This approach significantly reduced possible interference from  $\text{NO}_3^-$ .

<sup>a</sup>  $A/V$  is the ratio of CCC film area to solution volume,  $m/V$  is the ratio of mixed oxide weight to solution volume.

<sup>b</sup>  $\text{Cr}^{\text{VI}}$  concentration observed after reaching an apparently constant value, at least 10 days after immersion.

The adsorption of aqueous  $\text{Cr}^{\text{VI}}$  by  $\text{Cr}^{\text{III}}$ -hydroxide was studied by adding  $[\text{Cr}^{\text{VI}}]$  solution to solid  $\text{Cr}(\text{OH})_3$  prepared as described previously.<sup>12</sup> A known amount (0.1 to 1.0 g) of  $\text{Cr}(\text{OH})_3$  was combined with 50.0 mL of  $[\text{Cr}^{\text{VI}}]$  solution with known concentration and pH in a sealed vial which was shaken occasionally thereafter. Aliquots of solution were withdrawn periodically, centrifuged, quantitatively diluted with 2 M NaOH, and analyzed spectrophotometrically at 373 nm. Details about the mass of  $\text{Cr}^{\text{III}}$ -hydroxide and initial/final  $[\text{Cr}^{\text{VI}}]$  are listed in Table II.

The dynamic interaction between  $\text{Cr}^{\text{III}}$ -hydroxide and  $\text{Cr}^{\text{VI}}$  was studied as follows. A mixture of 0.062 M (as  $\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ ) and 0.019 M  $\text{Cr}^{\text{VI}}$  (as  $\text{K}_2\text{Cr}_2\text{O}_7$ ) was prepared. The total volume was 500 mL and the initial pH was below 3. In the first cycle, concentrated (~20 M) NaOH was added dropwise while agitating the solution. After each NaOH addition, the solution was stirred until the pH stabilized to  $\pm 0.1$  pH unit. 10 mL of the suspension was centrifuged for 5 min, then 1.00 mL aliquot of supernatant solution was quantitatively diluted to 50.00 mL by 2 M NaOH and analyzed spectrophotometrically. The remaining supernatant solution and solid was returned to the original 500 mL volume of solution. NaOH was added repeatedly such that spectra were obtained at 0.5 ~ 1.0 pH unit increments. Spectra were obtained after aliquots were diluted with NaOH, since the  $\text{NO}_3^-$  band (310 nm) overlaps with  $\text{Cr}^{\text{VI}}$  bands at acidic or neutral pH. After reaching a pH of 12, the process was reversed by incremental addition of concentrated  $\text{HNO}_3$  until the pH was less than 3. A second complete cycle of NaOH and  $\text{HNO}_3$  addition was conducted, in order to demonstrate reversibility. A similar experiment was carried out by using  $\text{Cr}_2\text{O}_3$ , instead of  $\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ .

Figure 3.  $\text{Cr}^{\text{VI}}$  concentration determined from the absorbance at 339 nm as a function of time after immersion of a CCC in nanopure water. Curves are labeled with the ratio of the geometric CCC area to solution volume.

## Results

When a CCC was immersed in water or salt solution, the  $\text{Cr}^{\text{VI}}$  concentration in solution increased with time, as shown in Fig. 3. The  $\text{Cr}^{\text{VI}}$  is a mixture of  $\text{CrO}_4^{2-}$ ,  $\text{Cr}_2\text{O}_7^{2-}$ , and  $\text{HCrO}_4^-$ , depending on concentration and pH, but the absorbance at 339 nm permits assessment of total

$\text{Cr}^{\text{VI}}$  in solution. All release curves of the type shown in Fig. 3 eventually reached a constant  $\text{Cr}^{\text{VI}}$  concentration after several days, and these limiting concentrations are listed in Table I for a variety of initial conditions. Several observations deserve special note. First, a higher ratio of CCC area to solution volume led to higher  $[\text{Cr}^{\text{VI}}]$  in solution. Second, aging of the CCC before exposure to water decreased the final  $[\text{Cr}^{\text{VI}}]$ , but not greatly. Third, the  $[\text{Cr}^{\text{VI}}]$  observed in 0.1 M NaCl was higher than that in deionized water, by approximately 26%, as shown in Fig. 4.

Release of  $\text{Cr}^{\text{VI}}$  from  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide was studied by adding known weights of synthetic mixed oxide to known volumes of water or salt solution, followed by spectrophotometric monitoring. Release curves similar to those of Fig. 3 and 4 were observed, and the final concentrations are listed in Table I. As was the case with the CCC, the final  $[\text{Cr}^{\text{VI}}]$  after release from the synthetic mixed oxide was in the range of  $10^{-4}$  to  $10^{-3}$  M, decreased with aging time, and was slightly higher in 0.1 M NaCl than in water. Table I also lists the final concentration of  $[\text{Cr}^{\text{VI}}]$  released from solid  $\text{SrCrO}_4$  into water and 0.1 M NaCl. For both the mixed oxide and  $\text{SrCrO}_4$ , solid remained after reaching the final  $[\text{Cr}^{\text{VI}}]$  level. The ratio of the final  $[\text{Cr}^{\text{VI}}]$  observed in water to that in 0.1 M NaCl ranged from 0.60 for  $\text{SrCrO}_4$ , 0.5-0.7 for the CCC, to 0.79 for the mixed oxide. This ratio did vary somewhat with aging time and A/V ratio, but was consistently in the range of 0.6 to 0.8 for all three starting materials. The activity coefficient of the dominant  $\text{Cr}^{\text{VI}}$  species in solution ( $\text{HCrO}_4^-$ ) in 0.1 M NaCl is 0.769, calculated from the extended Debye-Huckle equation.<sup>13</sup> The experimental ratios are very close to this calculated value, implying that the higher concentration observed in NaCl is due to a reduced activity coefficient.

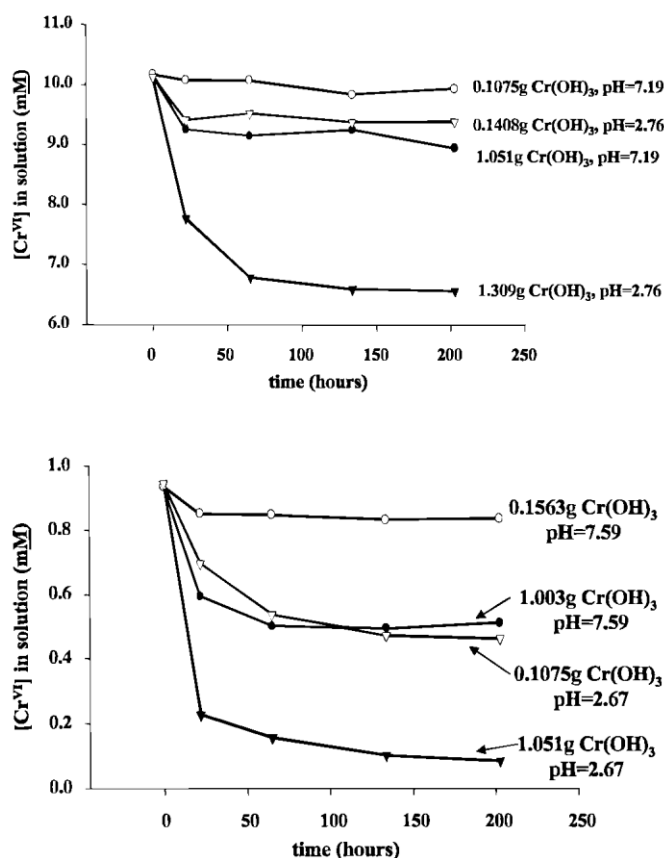

Figure 4.  $[\text{Cr}^{\text{VI}}]$  vs. time curves for  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide immersed in nanopure water or 0.10 M NaCl. 3.2 mg of mixed oxide was present per milliliter of solution, and then aged for the periods indicated.

If the constant  $[\text{Cr}^{\text{VI}}]$  observed at long times in Fig. 3 and 4 represents an equilibrium between solution and solid  $\text{Cr}^{\text{VI}}$ , then  $\text{Cr}^{\text{III}}$  oxide should adsorb  $\text{Cr}^{\text{VI}}$  from solution, according to Reaction 1

Reaction 1 is a simplified form of a reaction proposed in a previous report to represent a dynamic equilibrium between the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide and aqueous  $\text{Cr}^{\text{VI}}$ ,<sup>12</sup> and the remaining bonds to  $\text{Cr}^{\text{III}}$  are not shown to improve clarity.  $\text{CrO}_4^{2-}$  is used as an example of  $\text{Cr}^{\text{VI}}$  (aq); similar equilibria by using  $\text{HCrO}_4^-$  (aq),  $\text{Cr}_2\text{O}_7^{2-}$  (aq) are also possible. As written, the reverse reaction describes release of  $\text{Cr}^{\text{VI}}$  into solution from the CCC or mixed oxide, while the forward reaction represents  $\text{Cr}^{\text{VI}}$  adsorption by  $\text{Cr}^{\text{III}}$  hydroxide. To test the forward reaction,  $\text{Cr}^{\text{III}}$  hydroxide was added to  $\text{Cr}^{\text{VI}}$  solution, and the  $\text{Cr}^{\text{VI}}$  in solution was monitored spectrophotometrically. Figure 5 and Table II show results for  $\text{Cr}^{\text{VI}}$  adsorption by  $\text{Cr}^{\text{III}}$  hydroxide for different pH values and different initial weights of  $\text{Cr}^{\text{III}}$  hydroxide. The solid  $\text{Cr}(\text{OH})_3$  did indeed adsorb  $\text{Cr}^{\text{VI}}$  from solution, and the solution concentration decreased to an apparently constant  $[\text{Cr}^{\text{VI}}]$  level. Table II lists several final  $\text{Cr}^{\text{VI}}$  concentrations for different initial conditions. Adsorption was more pronounced at lower pH, and for higher weights of  $\text{Cr}^{\text{III}}$  hydroxide.

**Figure 5.**  $[\text{Cr}^{\text{VI}}]$  observed over  $\text{Cr}^{\text{III}}(\text{OH})_3$  placed in 50 mL of solution which initially contained 10.0 mM  $[\text{Cr}^{\text{VI}}]$  (A, top) or 1 mM  $[\text{Cr}^{\text{VI}}]$  (B, bottom). The initial pH was adjusted to the value indicated with  $\text{HNO}_3$  or  $\text{NaOH}$ .  $\text{Cr}^{\text{III}}(\text{OH})_3$  was prepared freshly, and the weight indicated was added to the  $\text{Cr}^{\text{VI}}$  solution.

The dynamic nature of the equilibrium between dissolved and adsorbed  $\text{Cr}^{\text{VI}}$  was examined further by cycling the pH of a  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  solution, as described in the experimental section. As concentrated  $\text{NaOH}$  was added dropwise, to soluble  $\text{Cr}^{\text{III}}$  and  $\text{Cr}^{\text{VI}}$  salts, the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$

mixed oxide formed and was allowed to equilibrate at a given pH for about 2 h. The total  $[\text{Cr}^{\text{VI}}]$  was determined spectrophotometrically, and the pH was measured before adding another aliquot of NaOH and re-equilibration at a different pH. After reaching pH 10-12,  $\text{HNO}_3$  was added to decrease pH, and two complete pH excursions were carried out in this fashion. A plot of solution  $[\text{Cr}^{\text{VI}}]$  vs. pH is shown in Fig. 6. Each point was taken after the addition of concentrated NaOH or  $\text{HNO}_3$  and equilibration at a particular pH. A similar experiment starting with solid  $\text{Cr}_2\text{O}_3$  and  $\text{Cr}^{\text{VI}}$  solution exhibited no adsorption of  $\text{Cr}^{\text{VI}}$  from solution. To assure time for equilibration, the results shown in Fig. 6 were acquired over a period of 7 days.

$\text{Cr}^{\text{VI}}$  loading levels in  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed-oxide or CCC film were measured as described previously.<sup>12</sup> CCC film was dissolved in basic solution, or the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide was dissolved in concentrated  $\text{HNO}_3$ , then the pH of both was increased to >12 by adding NaOH. Spectrophotometric measurements show that CCC film (Alodine, 1 min on AA2024-T3) contains  $(1.03 \pm 0.17) \times 10^{-7} \text{ mol Cr}^{\text{VI}}/\text{cm}^2$  and  $\text{Cr}^{\text{III}}/\text{Cr}^{\text{VI}}$ -mixed-oxide contains  $(5.46 \pm 0.25) \times 10^{-4} \text{ mol Cr}^{\text{VI}}/\text{g}$ . Both results are the average of three trials.

## Discussion

Before considering the quantitative implications of the observations, some useful conclusions are available about  $\text{Cr}^{\text{VI}}$  storage and release. A simple hypothesis might be that  $\text{Cr}^{\text{VI}}$  is trapped in the CCC as a soluble salt, such as  $\text{K}_2\text{Cr}_2\text{O}_7$ . In this case, the soluble  $\text{Cr}^{\text{VI}}$  would merely dissolve when the CCC was exposed to solution, and the final  $[\text{Cr}^{\text{VI}}]$  in solution would be linear with the  $A/V$  ratio. This case is plotted as the depletion model of Fig. 7, for which the CCC (or mixed oxide) is merely a repository of a soluble  $\text{Cr}^{\text{VI}}$  salt. The  $x$  axis in Fig. 7 is the number of moles of  $\text{Cr}^{\text{VI}}$  in the CCC or mixed oxide divided by the solution volume, and is proportional to either the CCC area/volume ratio or the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide weight/volume ratio listed in Table I. This depletion model is inconsistent with the observations for two major reasons. First, the observed  $[\text{Cr}^{\text{VI}}]$  is not linear with  $x$  in Fig. 7. Second, the uptake of  $\text{Cr}^{\text{VI}}$  by  $\text{Cr}(\text{OH})_3$  indicates that  $\text{Cr}^{\text{VI}}$  is not completely soluble in the presence of the synthetic  $\text{Cr}^{\text{III}}$  oxide, or the mixed oxide present in the CCC.

Figure 6. Equilibrium  $[\text{Cr}^{\text{VI}}]$  observed for a solution containing 0.062 M  $\text{Cr}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and 0.019 M  $\text{Cr}^{\text{VI}}$  (as  $\text{K}_2\text{Cr}_2\text{O}_7$ ) following the addition of NaOH, then  $\text{HNO}_3$ . The pH was increased from ~3 to ~10 with NaOH, then decreased to ~2.5 with  $\text{HNO}_3$  to comprise cycle 1. Open circles indicate the equilibrium  $[\text{Cr}^{\text{VI}}]$  for a second complete cycle. Solid line is a fit to Eq. 3 with  $\beta = 10^{10}$ . See text for details.

A second possibility is a solubility model, in which the  $\text{Cr}^{\text{VI}}$  concentration over a CCC or the mixed oxide is controlled by a solubility product, analogous to the case for  $\text{SrCrO}_4$ . Ignoring reactions of  $\text{CrO}_4^{2-}$  with  $\text{H}^+$  or  $\text{H}_2\text{O}$ ,  $\text{SrCrO}_4$  should behave as a simple sparingly soluble salt, with a saturation concentration determined by its solubility product ( $K_{\text{sp}} = 2.2 \times 10^{-5}$ ). The behavior of the solubility model is also shown in Fig. 7. Once sufficient  $\text{Cr}^{\text{VI}}$  was available to reach the solubility limit (4.7 mM), the solution would saturate and the addition of more  $\text{SrCrO}_4$  would have no further effect on  $[\text{Cr}^{\text{VI}}]$  in solution. If the CCC or mixed oxide followed this behavior, we expect a saturation level of  $\text{Cr}^{\text{VI}}$  which could not be exceeded by adding more CCC (increased  $A/V$ ) or mixed oxide. However, this is not the case, with increasing  $A/V$  always resulting in higher  $[\text{Cr}^{\text{VI}}]$  in solution. The solubility model is likely to apply to  $\text{SrCrO}_4$  contained in the primer, but not to the CCC or the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide.

It is clear that the release of  $\text{Cr}^{\text{VI}}$  from the CCC (or mixed oxide) is reversible and pH dependent, and strongly dependent on the initial amount of  $\text{Cr}^{\text{VI}}$  in the CCC or mixed oxide relative to the solution volume. A mechanism that is consistent with the observations is adsorption of  $\text{Cr}^{\text{VI}}$  species to the insoluble  $\text{Cr}^{\text{III}}$  hydroxide, shown schematically in Fig. 8. We consider the insoluble  $\text{Cr}^{\text{III}}$  to have many surface hydroxyl groups available for formation of  $\text{Cr}^{\text{III}}\text{-O-Cr}^{\text{VI}}$  bonds. These hydroxyl groups act as sites for covalent binding of  $\text{Cr}^{\text{VI}}$  according to Eq. 1.  $\text{Cr}^{\text{III}}\text{-OH}$  (solid) in Eq. 1 represents insoluble  $\text{Cr}^{\text{III}}$  hydroxide,  $\text{Cr}^{\text{VI}}\text{O}_4^{2-}$  (aq) is solution-phase hexavalent chromium,  $\text{Cr}^{\text{III}}\text{-O-Cr}^{\text{VI}}$  is the mixed oxide present in the CCC or prepared synthetically depending on pH and concentration. Solution-phase  $\text{Cr}^{\text{VI}}$  may be  $\text{CrO}_4^{2-}$ ,  $\text{HCrO}_4^-$ , or  $\text{Cr}_2\text{O}_7^{2-}$ . Reaction 1 is reversible, so the CCC may release  $\text{Cr}^{\text{VI}}$ , and the  $\text{Cr}^{\text{III}}$  hydroxide may adsorb  $\text{Cr}^{\text{VI}}$  from solution. Release and adsorption of  $\text{Cr}^{\text{VI}}$  are pH dependent, favoring the mixed oxide at low pH and soluble  $\text{Cr}^{\text{VI}}$  at higher pH, as observed experimentally (Fig. 6). Furthermore, the number of hydroxyl groups in  $\text{Cr}^{\text{VI}}$ -hydroxide which may be exchanged for  $\text{Cr}^{\text{VI}}$  is finite, resulting in a saturation level of  $\text{Cr}^{\text{VI}}:\text{Cr}^{\text{III}}$  of approximately 1:3. The equilibrium for a solution species binding to a finite number of sites on a solid is mathematically similar to Langmuir adsorption behavior as represented by Eq. 2.<sup>18</sup> The insoluble  $\text{Cr}^{\text{VI}}$  oxide is a porous solid containing  $\text{Cr}^{\text{VI}}$  binding sites rather than the flat surface normally associated with Langmuir behavior, but it does exhibit a nonlinear relationship between solution and surface concentration consistent with Eq. 2. If we consider the  $\text{Cr}^{\text{III}}$  oxide matrix in the CCC or mixed oxide to have a finite surface area for adsorption with a saturation coverage of adsorbed  $\text{Cr}^{\text{VI}}$  to equal to  $\Gamma_s$ , then

$$\frac{\Gamma_{\text{VI}}}{\Gamma_s - \Gamma_{\text{VI}}} = \beta[\text{Cr}^{\text{VI}}][\text{H}^+] = \frac{\theta_{\text{VI}}}{1 - \theta_{\text{VI}}} \quad [2]$$

where  $\Gamma_{\text{VI}}$  is the coverage of  $\text{Cr}^{\text{VI}}$  on the  $\text{Cr}^{\text{III}}$  oxide in  $\text{mol}/\text{cm}^2$ ,  $\beta$  is a binding constant, and  $\theta_{\text{VI}}$  is the fractional coverage of  $\text{Cr}^{\text{VI}}$ . Note that the area relevant to adsorption is the microscopic area of the  $\text{Cr}^{\text{III}}$  oxide matrix, not of the CCC itself. Although this microscopic area is difficult to determine, we assume it to be proportional to the geometric CCC area or to the mass of synthetic mixed oxide. If we define  $N_{\text{VI}}$  as the moles of  $\text{Cr}^{\text{VI}}$  present in the CCC or mixed oxide solid,  $N_{\text{VI}}$  may be calculated after assuming a homogeneous distribution of  $\text{Cr}^{\text{VI}}$  in the solid. For the CCC,  $N_{\text{VI}}$  equals the initial average  $\text{Cr}^{\text{VI}}$  concentration ( $\text{mol}/\text{geometric cm}^2$ ) times the CCC geometric area. For the mixed oxide,  $N_{\text{VI}}$  equals the initial  $\text{Cr}^{\text{VI}}$  loading ( $\text{mol}/\text{gram}$ ) times the weight of mixed oxide.

Figure 7. Predicted behavior of  $[\text{Cr}^{\text{VI}}]$  as a function of  $\text{Cr}^{\text{VI}}$  loading in a CCC or mixed oxide for the solubility, depletion, and adsorption mechanisms of  $\text{Cr}^{\text{VI}}$  release.  $N_{\text{VI}}/V$  is the ratio of the moles of  $\text{Cr}^{\text{VI}}$  in the solid to the solution volume. The  $K_{\text{sp}}$  is that of  $\text{SrCrO}_4$ , and is used only to illustrate the shape of the curve.

Figure 8. Model for adsorption of  $\text{Cr}^{\text{VI}}$  to solid  $\text{Cr}^{\text{III}}$  hydroxide, based on Eq. 1.  $\text{Cr}^{\text{VI}}$  is shown as  $\text{CrO}_4^{2-}$ , but may also exist as  $\text{HCrO}_4^{-2}$  or  $\text{HCr}_2\text{O}_7^{-2}$ , depending on pH and  $[\text{Cr}^{\text{VI}}]$ . Gray area represents insoluble  $\text{Cr}^{\text{III}}$  matrix which is permeable by water and solution phase  $\text{Cr}^{\text{VI}}$ .

Under the assumption that Eq. 2 controls the  $\text{Cr}^{\text{VI}}$  (aq) concentration of a solution in equilibrium with a CCC or mixed oxide, predictions of the behavior of  $[\text{Cr}^{\text{VI}}]$  for several situations may be derived. When  $\text{Cr}^{\text{VI}}$  (aq) is desorbed from an initially saturated CCC or mixed oxide, the  $[\text{Cr}^{\text{VI}}]$  follows Eq. 3, with  $V$  representing solution volume (see Appendix for derivation)

$$[\text{Cr}^{\text{VI}}]_{\text{equil}} = \frac{-1 + \sqrt{1 + 4\beta[\text{H}^+]N_{\text{VI}}/V}}{2\beta[\text{H}^+]} \quad [3]$$

The observed pH at the end of release experiments was  $4.6 \pm 0.7$ . A fit of Eq. 3 to the equilibrium values of  $[\text{Cr}^{\text{VI}}]$  listed in Table I is shown in Fig. 9. Results for the CCC on both AA2024 and AA1100, as well as for the synthetic  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide are shown, along with curves predicted from Eq. 3 for three values of the product  $\beta[\text{H}^+]$ . As noted earlier, the model assumes that  $\text{Cr}^{\text{VI}}$  permeates the CCC and is able to adsorb to its microscopic area. This permeation process certainly affects the release kinetics, but Eq. 3 requires only that the entire CCC or mixed oxide has equilibrated with the solution. The release kinetics will be discussed in a separate publication.

Figure 9. Results of release experiments from a CCC on both AA1100 and AA2024-T3, and the  $\text{Cr}^{\text{III}}/\text{Cr}^{\text{VI}}$  mixed oxide. Lines are calculated from Eq. 3 with the indicated values of the product  $\beta[\text{H}^+]$ .  $N_{\text{VI}}/V$  is the ratio of adsorbed moles of  $\text{Cr}^{\text{VI}}$  to the solution volume.

The adequate fit of the experimental data to Eq. 3 with  $\beta[\text{H}^+] = 10^3$  provides support for a saturable adsorption process similar to Langmuir adsorption as the equilibrium which controls  $[\text{Cr}^{\text{VI}}]$ . One cannot rigorously exclude other mechanisms, but at least the results are consistent with Langmuir adsorption, and not with the solubility or depletion models. Based on the solution pH observed for  $\text{Cr}^{\text{VI}}$  release from a CCC or mixed oxide ( $4.6 \pm 0.7$ ), the fit shown in Fig. 9 corresponds to a  $\beta$  value of  $10^7$ - $10^{10}$ . Several observations about Eq. 3 and Fig. 9 deserve note. First, the agreement between the results from the CCC on different alloys and the synthetic mixed oxide implies that the same chemistry controls the release process. As stated previously,<sup>12</sup> we believe the CCC consists of a porous  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide that can slowly release  $\text{Cr}^{\text{VI}}$  into solution. Second, there is a finite number of binding sites for  $\text{Cr}^{\text{VI}}$  on the insoluble  $\text{Cr}^{\text{III}}$  oxide matrix of a CCC, and the sites can be saturated. The high  $\text{Cr}^{\text{VI}}$  concentration and low pH present during CCC formation promotes  $\text{Cr}^{\text{VI}}$  adsorption and favors saturation of the matrix. Third,  $\text{Cr}^{\text{VI}}$  binding is strongly pH dependent, as is consistent with Fig. 6. The solid line in Fig. 6 was calculated from Eq. 3, and indicates reasonable agreement with experimental results. This dependence is a simple and predictable consequence of Reaction 1, in which high  $[\text{H}^+]$  favors  $\text{Cr}^{\text{VI}}$  binding. Fourth, the equilibrium  $[\text{Cr}^{\text{VI}}]$  has an unusual square-root dependence on  $N_{\text{VI}}$  (and therefore on the  $A/V$  ratio). Unlike a solubility mechanism, in which the solution reaches a saturation level, the  $[\text{Cr}^{\text{VI}}]$  predicted from Eq. 3 increases with  $(A/V)$  without bound. In reality, an upper limit of  $[\text{Cr}^{\text{VI}}]$  will occur at saturation when a  $\text{Cr}_2\text{O}_7^{2-}$  salt or  $\text{CrO}_3$  precipitate, but this level is much higher ( $>0.1$  M) than those observed during release experiments. In chemical terms, the square root dependence on  $A/V$  stems from the fact that the activity of adsorbed  $\text{Cr}^{\text{VI}}$  changes as release occurs, while the activity of a slightly soluble solid remains constant. Unlike the case for  $\text{SrCrO}_4$  solubility, release of  $\text{Cr}^{\text{VI}}$  from the CCC affects both the  $\text{Cr}^{\text{VI}}$  activity in solution and adsorbed on the  $\text{Cr}^{\text{III}}$  matrix.

Solution of Eq. 2 for the case of an initial quantity of solid  $\text{Cr}^{\text{III}}$  hydroxide exposed to  $\text{Cr}^{\text{VI}}$  solution yields Eq. 4 (see Appendix for details)

$$[\text{Cr}^{\text{VI}}] = \frac{-z + \sqrt{z^2 + 4\beta[\text{H}^+][\text{Cr}^{\text{VI}}]_{t=0}}}{2\beta[\text{H}^+]} \quad [4]$$

$$z = 1 + \beta[\text{H}^+] \left( \frac{N_{\text{VI}}^{\text{max}}}{V} \right) - \beta[\text{H}^+][\text{Cr}^{\text{VI}}]_{t=0}$$

where  $N_{\text{VI}}^{\text{max}}$  is the moles of  $\text{Cr}^{\text{VI}}$  adsorbed to the  $\text{Cr}^{\text{III}}$  hydroxide at saturation, and  $[\text{Cr}^{\text{VI}}]_{t=0}$  is the initial  $[\text{Cr}^{\text{VI}}]$  in solution. The experimental results of Fig. 6 are consistent with Eq. 4 and Eq. 3, and a  $\beta$  value of  $10^9$ . For the results listed in Table II, there was significant variation in the equilibrium pH for different initial amounts of  $\text{Cr}^{\text{III}}$  hydroxide. The fairly wide spread of final pH values (about 3 pH units) prevented a reliable fit of the results to Eq. 4.

*Implications to corrosion protection.*—The current results provide additional support for previous conclusions about CCC chemistry, and add some new insights into chromate storage and release. The Langmuir adsorption model is completely consistent with  $\text{Cr}^{\text{VI}}$  storage in a CCC as a  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide,<sup>12</sup> according to Reaction 1. The large binding constant of  $10^7\text{-}10^{10}$  implies a strong bond between  $\text{Cr}^{\text{III}}$  and  $\text{Cr}^{\text{VI}}$ . For comparison, “chemisorption” is considered to have a  $\Delta G^\circ$  of adsorption more negative than  $-40$  kJ/mol, corresponding to a binding constant of  $>10^7$ , while physisorption has a  $\Delta G^\circ$  above  $-25$  kJ/mol ( $\beta < 2 \times 10^4$ ).<sup>19</sup> The  $\beta$  value estimated from Fig. 9 ( $10^7\text{-}10^{10}$ ) corresponds to chemisorption, implying a relatively strong covalent bond. As noted earlier, the pH dependence of  $\text{Cr}^{\text{VI}}$  binding apparent in Fig. 6 favors  $\text{Cr}^{\text{VI}}$  binding during CCC formation (low pH and high  $[\text{Cr}^{\text{VI}}]$ ) and  $\text{Cr}^{\text{VI}}$  release in a defect in the field (low  $[\text{Cr}^{\text{VI}}]$ , neutral pH). The storage and release of  $\text{Cr}^{\text{VI}}$  is likely to be critical to the ability of chromate coatings to passivate defects, scratches, etc. While self-healing may also result from  $\text{Cr}^{\text{VI}}$  released by the  $\text{SrCrO}_4$  containing primer, the two processes are controlled by different equilibria. The finite solubility of  $\text{SrCrO}_4$  ( $\sim 5$  mM) implies that  $\text{SrCrO}_4$  will dissolve until this limit is reached, perhaps leading to complete dissolution and depletion of the  $\text{SrCrO}_4$  exposed to the environment. The Langmuir adsorption operative in the CCC does not result in a constant  $[\text{Cr}^{\text{VI}}]$ , but rather one that decreases as the CCC film is depleted. Although the released  $[\text{Cr}^{\text{VI}}]$  decreases as the CCC is depleted, an equilibrium can be maintained at very low levels of both adsorbed and solution  $\text{Cr}^{\text{VI}}$ . Depending upon the  $[\text{Cr}^{\text{VI}}]$  level required for self-healing, and the relative amounts of  $\text{Cr}^{\text{VI}}$  in CCC and primer, the CCC may outlast a  $\text{SrCrO}_4$  primer, since the CCC will release less  $\text{Cr}^{\text{VI}}$  as it becomes depleted.

The effect of ionic strength on  $\text{Cr}^{\text{VI}}$  release is attributable to an activity effect. The activity coefficient calculated for  $\text{CrO}_4^{2-}$  in 0.1 M NaCl quantitatively accounts for the higher equilibrium  $[\text{Cr}^{\text{VI}}]$  in NaCl, at least to the accuracy expected from the extended Debye-Huckel equation.<sup>13</sup> The current results do not take  $\text{Cr}^{\text{VI}}$  speciation into account, except for the spectrophotometric analysis described in Fig. 1 and 2. The distribution of solution  $\text{Cr}^{\text{VI}}$  between  $\text{HCrO}_4^-$ ,  $\text{Cr}_2\text{O}_7^{2-}$ ,  $\text{CrO}_4^{2-}$ , and even  $\text{H}_2\text{CrO}_4$  may affect the binding constant  $\beta$ . The dominant  $\text{Cr}^{\text{VI}}$  species in the conditions used here is  $\text{HCrO}_4^-$ , but the adsorption equilibria may vary above pH 6.5 or below pH 2. The value of  $\beta$  and the nature of the adsorbed  $\text{Cr}^{\text{VI}}$  may vary under these conditions, but Langmuir adsorption is still expected to prevail.

An additional issue of importance to the applications of CCCs involves aging after CCC formation. Aging of both the CCC on AA 2024-T3 and the  $\text{Cr}^{\text{III}}\text{-Cr}^{\text{VI}}$  mixed oxide for periods from 0.25 to 210 h at room temperature decreased the equilibrium  $[\text{Cr}^{\text{VI}}]$  released into water (Table I). However, the decrease in  $\text{Cr}^{\text{VI}}$  release was not large; about 25% for the CCC and 40%

for  $\text{Cr}^{\text{III}}/\text{Cr}^{\text{VI}}$  mixed oxide. A much greater decrease in  $\text{Cr}^{\text{VI}}$  release occurred after the CCC was heated at  $50^\circ\text{C}$  in air for 1 h. These decreases could be due to a reduction in CCC hydration or to a structural rearrangement that tightly binds  $\text{Cr}^{\text{VI}}$ .

In conclusion, the adsorption and release of  $\text{Cr}^{\text{VI}}$  from a CCC is consistent with adsorption of  $\text{CrO}_4^{2-}$ ,  $\text{HCrO}_4^-$  or  $\text{Cr}_2\text{O}_7^{2-}$  to a porous, insoluble  $\text{Cr}^{\text{III}}$  hydroxide matrix. Adsorption is saturable, reversible, and pH dependent, with higher pH favoring desorption of  $\text{Cr}^{\text{VI}}$ . The low pH and relatively high  $[\text{Cr}^{\text{VI}}]$  in a CCC formation path favor adsorption of  $\text{Cr}^{\text{VI}}$  to the  $\text{Cr}^{\text{III}}$  matrix formed by reduction of  $\text{Cr}^{\text{VI}}$  to the  $\text{Cr}^{\text{III}}$  by the alloy. The observations are quantitatively similar to a Langmuir adsorption-desorption equilibrium with a binding constant of  $10^7$ - $10^{10}$  for the  $\text{Cr}^{\text{VI}}$  interaction with  $\text{Cr}^{\text{III}}$  hydroxide. This high binding constant supports an adsorption mechanism based on formation of a covalent  $\text{Cr}^{\text{III}}\text{-O-Cr}^{\text{VI}}$  bond. Unlike traditional Langmuir adsorption to a surface, however,  $\text{Cr}^{\text{VI}}$  binding to  $\text{Cr}^{\text{III}}$  oxide occurs throughout the entire porous  $\text{Cr}^{\text{III}}$  film.

## Appendix

*Release of  $\text{Cr}^{\text{VI}}$  from CCC.*—Starting with Eq. 2 from the main text, we note that  $\Gamma_s$  is the initial coverage of  $\text{Cr}^{\text{VI}}$  in the CCC, ( $\text{mol}/\text{cm}^2$ ) and  $\Gamma_{\text{VI}}$  is the equilibrium coverage. Once equilibrium is reached

$$[\text{Cr}^{\text{VI}}] = \frac{(\Gamma_s - \Gamma_{\text{VI}})A}{V} \quad [\text{A-1}]$$

and

$$\Gamma_{\text{VI}} = \Gamma_s - [\text{Cr}^{\text{VI}}]V/A \quad [\text{A-2}]$$

since the released  $\text{Cr}^{\text{VI}}$  enters the solution as soluble  $\text{Cr}^{\text{VI}}$ . Substitution of  $\Gamma_s$  and  $\Gamma_{\text{VI}}$  from Eq. A-2 into Eq. 2 yields

$$[\text{Cr}^{\text{VI}}] + \frac{[\text{Cr}^{\text{VI}}]}{\beta[\text{H}^+]} - \frac{A\Gamma_s}{V\beta[\text{H}^+]} = 0 \quad [\text{A-3}]$$

Application of the quadratic formula and assignment of  $\Gamma_s A$  as  $N_{\text{VI}}$ , the initial moles of  $\text{Cr}^{\text{VI}}$  in the CCC, yields Eq. 3 in the main text.

*Release of  $\text{Cr}^{\text{VI}}$  from mixed oxide.*—Solution of Eq. 2 for the  $\text{Cr}^{\text{III}}/\text{Cr}^{\text{VI}}$  mixed oxide also yields Eq. 3, except the surface area of  $\text{Cr}^{\text{III}}$  in the solid is unknown. However,  $N_{\text{VI}}$  has the same meaning and can be calculated as the weight of oxide times the initial  $\text{Cr}^{\text{VI}}$  concentration in the oxide in terms of moles/gram.

*Adsorption of  $\text{Cr}^{\text{VI}}$  to synthetic  $\text{Cr}^{\text{III}}$  hydroxide.*—The area available for adsorption on the  $\text{Cr}^{\text{III}}$  hydroxide matrix is unknown, but is assumed to be proportional to the mass of  $\text{Cr}^{\text{III}}$  hydroxide,  $m$ , by some constant  $k$ , so that  $A = km$ . Starting with an initial  $\text{Cr}^{\text{VI}}$  in solution of  $[\text{Cr}^{\text{VI}}]_{t=0}$ , the equilibrium coverage of  $\text{Cr}^{\text{VI}}$  is

$$\Gamma_{\text{VI}} = \frac{([\text{Cr}^{\text{VI}}]_{t=0} - [\text{Cr}^{\text{VI}}])V}{mk} \quad [\text{A-4}]$$

Substitution of  $\Gamma_{\text{VI}}$  from Eq. A-4 into Eq. 2 yields

$$[\text{Cr}^{\text{VI}}]_{t=0} - [\text{Cr}^{\text{VI}}] = \frac{\beta[\text{Cr}^{\text{VI}}][\text{H}^+](\Gamma_{\text{max}}mk)}{(1 + \beta[\text{Cr}^{\text{VI}}][\text{H}^+])^{1/\nu}} = 0 \quad [\text{A-5}]$$

$\Gamma_{\text{max}}$  is the maximum loading of the  $\text{Cr}^{\text{III}}$  hydroxide, and differs from  $\Gamma_s$  for the CCC only in its relationship to microscopic rather than geometric area. The total moles of adsorbed  $\text{Cr}^{\text{VI}}$ ,  $N_{\text{VI}}^{\text{max}}$ , is

$$N_{\text{VI}}^{\text{max}} = \Gamma_{\text{max}}mk \quad [\text{A-6}]$$

Substitution of Eq. A-6 into A-5 and solving for  $[\text{Cr}^{\text{VI}}]$  yields Eq. 4 in the main text.
